# CATCHING GREAT AIR

A research scientist documents the remarkable aerodynamic adaptations of northern flying squirrels.

# ARTICLE AND PHOTOGRAPHS BY

## **ALEXANDER V. BADYAEV**

spent the day in my research cabin north of Ovando in the Blackfoot River Valley poring through photographic equipment manuals to determine the lowest temperature of operation. Meanwhile, the radio was broadcasting severe winter weather warnings, with dangerously low overnight temperatures. Finally, I decided on a plan and headed into the forest.

A few hours later, after snowshoeing 6 or 7 miles into the backcountry, I stopped and began working in the diminishing February twilight. As quickly as possible in the freezing cold, I strung a rope of strobe lights along the branches of several trees. The lights were connected to a high-speed camera set on the ground and aimed at a gap in the tree canopy. The trees framed a tiny halfacre forest pond on the southern boundary of the Bob Marshall Wilderness. From previous field research by my graduate students and me. I knew that local female northern flying squirrels regularly travel along the shore of the pond. In winter, the squirrels emerge from roosting cavities shortly after midnight and range throughout the forest, traveling to their under-snow food caches by remarkably consistent routes. My goal was to photograph squirrels in flight in a natural context, something rarely documented.

Based on my previous observations, I expected one of the female squirrels I'd targeted to fly over the pond between 2:20 a.m. and 2:50 a.m. Unfortunately, the overnight temperature was predicted to plummet to -40 degrees F, greatly increasing the chance of camera failure. But the risks were worth it. In Montana, February is the middle of the northern flying squirrel's mating season. Even in severe cold, each female is typically escorted through the forest by a squabbling squadron of ardent males. I was hoping also to photograph those males and their dizzying aerial mating chases.

LAUNCHING SKYWARD To quickly gain elevation, flying squirrels push from the ground using powerful hind legs before opening their flying membrane and gliding to a nearby tree. Here a flying squirrel bursts from its cache of fir cones buried deep in the snow, leaving a potential intruder startled while gliding away to safety. "Walking through the forest at night, it's like champagne bottle corks popping around you," says the author. Such escapes are far less successful with raptors. Flying squirrels rustling noisily under snow become too confident in their explosive escape strategy and end up a staple winter food of great horned owls.

PREPARE FOR LANDING A flying squirrel's flattened tail adds an additional 25 percent of gliding surface. Just before landing, the squirrel drops its hips, opening up the patagia—the membranes on each side of its body—into a speed-slowing parachute and bringing the hind feet forward.

### HIGH FLYER

The northern flying squirrel is one of two flying squirrel species in North America. The other is the smaller but almost identical southern flying squirrel. The species in Montana ranges across Canada and Alaska through the northern Rockies and Great Lakes states, down to Appalachia's cooler great gray owls, their primary predators. mountain zones as far south as North Car- The squirrel's role as a central link in the olina. His recent photos are featured in a new book, Mammals of Montana.

ing squirrels were passive aerialists that used their gliding ability simply to prolong jumps across canopy gaps and lessen the impact of landing.

These assumptions recently became suspect, however, when laboratory studies uncovered several exceptional features of squirrel aerodynamics that strongly hinted the species might be capable of more than passive gliding. Time-lapse lab photos indicated that flying squirrels conducted airborne feats that aerodynamic theory The flying squirrel is well known for its suggested should be impossible for a species simply gliding through air.

In particular, studies found that airborne squirrels have an unusually high "angle of attack"—the angle between the gliding membrane and the direction of oncoming airflow. While greater angles generate greater lift, valuable for gaining midair height and distance, the angles observed in flying squirrels far exceed those sustained even by advanced military jets. In theory, the high angle should cause the

soaring squirrel to stall midair and crash.

Scientists also found that somehow the squirrels are able to eliminate the destabi- hoped to answer as I knelt in the snow that lizing forces of unequal air pressure above frigid February night. and below the patagia. But that doesn't seem branches of a spruce tree high over my head. the case. How do they do it?

Scientists have also wondered why flying squirrels don't crash. Simple calculations show that a squirrel landing from a routine 40-foot glide would hit a tree with the pond—seemingly without much loss of from across the frozen expanse, occasionan impact of more than 30 times its body weight unless it actively stalls well in advance of the landing. Yet such a stall would further decrease flight stability and dura- covered branch against a tree trunk, intion. Based on what's known about aerodynamics, flying squirrels should be confined stant crashes, stalls, and falls. Yet they soar a nearby tree, somehow steering the end of long flights across open fields; midair

great distances. How is that possible?

MORE THAN JUST SOAR Scientists once thought flying squirrels could not actually fly but only glided, passively. Now researchers are thinking other-

wise. Though the squirrels don't flap their patagia, they slightly adjust parts of their anatomy to increase lift and decrease air turbulence.

Those were just some of the questions I

It began with a cloud of snow kicked up by about 10 feet. Then she spread the memtwo males chasing each other on the upper branes wide open and, lighted by a series of One lost his grip then dove into a long glide camera, seemed to freeze in midair for a over the pond, followed immediately by the moment before gracefully gliding out of second male in a rapidly accelerating glide.
